Unserver, A. C. Dark. Recorder, E. P. Herendeen.]

[June 24, 1882, midnight. Theodolite, Fauth & Co. Chronometer, I. Observer, A. C. Dark. Recorder, E. P. Herendeen. The times given do not correspond to the time of lower culmination of the sun; therefore the mean of the four smallest readings (supposed to indicate the time of lower culmination) were taken. The discordance between the results at upper and lower culminations seems to indicate that the instrument was not adjusted for index error.]

Observed attitudes.

## APPENDIX No. 2.

OBSERVATIONS MADE AT WASHINGTON, D. C., IN 1881 AND 1884, FOR DETERMINING THE CONSTANTS OF THEODOLITE MAGNETOMETER NO. AVAND OF KEW DIP CIRCLE NO. 23, TOGETHER WITH THE COMPUTATION AND A RECAPITULATION OF RESULTS.

[Computer: E. H. Courtenay.]

Observations to determine the value of one scale-division of the long magnet L<sub>ij</sub>, accompanying theodolite magnetometer No. 11, made at the Magnetic Observatory on Capitol Hill, Washington, D. C., ty M. Smith, in June, 1881, and by J. E. Maxfield, February 5, 1884.

DETERMINATION OF THE MOMENT OF MASS (M<sub>1</sub>) OF THE MASS RING ACCOMPANYING THEODO. LITE MAGNETOMETER NO. 11.

The mass ring accompanying theodolite magnetometer No. 11 is of brass or gun metal, and bas no distinguishing mark on it. Its weight was determined at the Coast and Geodetic Survey Office, by E. B. Lefavour, April 29, 1881, and found to be 300.767 grains.

The following measurements to determine the inner and outer diameters were made at the Coast and Geodetic Survey Office by Assistant C. A. Schott:

| 1881, April 29.  | Temp. 77° F.                                      | . 1881, April 30.                     | Темр. 78° Г.         |

#### APPENDIX No. 6.

MEMORANDUM RESPECTING MAGNETICALLY DISTURBED AND UNDISTURBED DAYS AT UGLA-AMIE, ALASKA, 1882-183.

COMPUTING DIVISION, COAST AND GEODETIC SURVEY, December 6, 1884.

A complete examination was made of the tabulated observations at Uglaamie of variations in declination and in the horizontal and vertical components of the earth's magnetism—for all those days on which disturbances were observed at other polar stations and for those days which were selected as normal or quiet days—according to circular No. 39, issued by Dr. Wild, president of the International Polar Commission.

Our series with the Brooke differential instruments commences with September 12, 1882, and for these instruments it was found that for every one of the 21 days, designated as disturbed at other stations, disturbances occurred at Ughamie in the declination and in the horizontal force and generally also in the vertical force, as may be seen in the accompanying list. Certain times, extending over several days, present themselves very prominently, and these may aptly be designated as times of stormy magnetic weather, suggesting their collective study.

Respecting the so-called quiet days (steady condition of magnetism) it is not so easy to make any positive statement, for the reason that the normal or undisturbed observations have not yet been reported and treated by themselves, hence only an indistinct idea as to the limits of variability can at present be had. In general the days mentioned as quiet were also found to be so at Uglamie, yet there are exceptions, and in particular the horizontal force appears to have been rather restless. The Uglamie record would exclude the following days from the table of quiet days and place them among those of ordinary ones, viz: 1882, September 30, declination and horizontal force agitated; 1883, February 8, ditto; March 15, declination, horizontal and vertical force agitated; May 15, horizontal and vertica force excited; June 11, ditto.

Respectfully submitted by

CHAS. A. SCHOTT,

Assistant

J. E. HILGARD,

Superintendent United States Coast and Geodetic Survey.

#### UGLAAMIE MAGNETIC RECORD, 1882-'83.

Examination of days of disturbance mentioned in Circular No. 39, issued by President Wild, November 8, 1884.

August 5, 1882 (Observation with inferior instrument).—Declination disturbance commenced August 4, and was dying out in the forenoon of August 5.

October 6, 1882.—Declination greatly disturbed. Horizontal force heavily disturbed. Vertical force slightly affected.

October 28, 1882.—Declination slightly disturbed, extending to the 29th. Horizontal force greatly disturbed on the 28th and 29th. Vertical force slightly affected.

November 12 and 13, 1882.—Declination greatly disturbed; continued to 14th. Strong auroral display on both days. Great disturbance of horizontal force on the 12th, 13th, 14th, and 15th. Vertical force disturbance excessive on 12th, 13th, and 14th.

0, 19692 0, 91759 1, 10851 9, 17483 0, 38334 November 17 to 20, 1882.—Declination greatly disturbed on these days; brilliant auroral display on the 20th. Great disturbance in horizontal force on the 17th, 18th, 19th, 20th, and 21st. Vertical force but little affected.

The magnetic equilibrium was disturbed during the entire period, November 12 to November 21, inclusive, with daily displays of auroras.

December 20, 21, 1882.—Declination disturbance commenced on the 19th and continued to the 24th, inclusive. Bright auroras every day. Horizontal force greatly disturbed on the 20th and 21st. Vertical force slightly, if at all, affected.

February 24, 25, 27, 28, 1883.—Declination disturbances commence February 22, and extend at least to March 3; daily auroras, very brilliant February 23, 25, 26, 28, March 2 and 3. Horizontal force on the 24th and 25th greatly disturbed (already on preceding days, 22d and 23d), and continues in a state of unrest to March 3, inclusive. The vertical force appears undisturbed on the 24th and 25th, and is but slightly affected on the 28th.

March 27, 1883.—Declination greatly disturbed on the 27th and 28th. Bright auroras on the 26th, 27th, and 28th. Days of disturbance of the horizontal force 26th, 27th, 28th, 29th, and 30th. Vertical force very little affected.

April 3, 1883.—Declination greatly disturbed April 2 and 3; auroras. Great disturbance in horizontal force on the 1st, 2d, 3d, 4th, and 5th. Vertical force slightly affected.

May 21, 22, 1883.—Declination disturbed on the 20th, 21st, and 22d; horizontal force likewise Vertical force disturbed on the 21st but not on the 22d.

June 18, 1883.—Declination greatly disturbed on the 17th, 18th, 19th; horizontal force disturbed on the 17th, 18th, 19th, and 20th. Vertical force apparently normal.

June 27, 1883.—Large disturbance in declination. Horizontal force disturbed on the 25th, 26th, 27th, 28th, 29th, and 30th, and very heavily on July 1. Vertical force apparently normal.

PART VII.

TIDES.

Tide Gauge at Uylaumie, Alaska,

F, F, F, frame. H, hele in ice. L, line. P. P. pulleys. C. counterpoise. S, scale. V, vernier.

## TIDES.

Observations of tides at the United States Itnernational Polar Station, Uglaamie, Alaska, were made half-hourly and uninterruptedly for a period of 112 days, beginning at midnight February 26, and ending with midnight June 17, 1883. This series, consisting of 5,376 observations, is complete, not a single reading being missed. These observations form a part of the general series of records secured at this station, and were made by the same observers as were the meteorological and magnetic observations.

Six observers were on duty daily, each making all the observations for four hours. These observers were Charles Ancor, A. C. Dark, J. A. Guzman, J. E. Maxfield, John Murdoch, and Middleton Smith. How faithfully these observers did their duty may be interred from the fact that not a single observation was missed. To make a tidal observation, the observer walked out over the level ice to the gauge, about 100 yards from the shore, broke through the ice in the hole formed since the last observation, a half-hour before, scooped out the slush so as to clear the line, and then read the scale to the nearest hundredth of a foot. Returning to the house, he wrote down this reading, together with the hour, the direction of the wind, and the initial of his name. He further noted whether the tide had turned since the last observation, and if so, the highest or lowest reading reached. This was done by means of a maximum and minimum index, to be described in connection with the gauge. When a maximum or minimum reading occurred between the half-hourly readings, this fact is noted in the record, but is not here reproduced, as it does not appear to much increase the knowledge afforded by the record as here printed. The record was kept in duplicate, the second or duplicate copy being made daily, and thus kept up with the original.

Although wind observations were made half-hourly in connection with these tidal observations, nevertheless it is believed that the regular hourly observations of wind and atmospheric pressure will afford all the necessary data for determining the fluctuations of sea-level due to meteorological causes; for these reasons the half-hourly observations are not here printed.

Gauge.—The gauge was constructed at the station in February, 1883, and put in position so that observations began on the 26th, as before mentioned. No photograph of the gauge was made, but a drawing to scale appears on the plate opposite, from which its method of operation will be readily understood.

FFF is a wooden frame-work standing on the ice over the hole II. A line, L, passes from the 200 pound anchor through the hole H over pulleys PP, and terminates at the counterpoise C; this counterpoise weighing about 20 pounds. A fixed wooden scale, S, attached to the frame of the gauge, was subdivided to feet and tenths and hundredths, and to the line was attached an index which, moving along the scale, gave readings showing the stage of the tide.

The zero of the scale was placed low down, and the numbers increased upward and downward from this zero. The numbers above zero were considered positive (+) and those below it negative (-). When the tide rose, the ice, the gauge, and all its appurtenances were litted up, and in such manner that the difference between any two index readings would indicate the change of level between the readings.

From the construction, as well as from observation, therefore, we see that *increasing* numbers indicate *rising* tide and *diminishing* numbers *falling* tide.

In order to record automatically the heights of high and low water, a self-registering index was adjusted as follows:

A piece of cod line was stretched along the face of the scale and led through an ivory stud attached to the counterpoise. This ivory stud coincided with the zero of the vernier or reading index. On either side of this stud cork slides were attached to the cod line and were pushed one up, the other down, with rising and falling tide, respectively. Attached to these corks were brass verniers moving along the scale and enabling close readings to be made. The highest and lowest readings of the scalevel falling between the regular half hourly observations were thus automatically recorded.

Location of gauge.—The gauge was placed on the shore ice due west from the station and at a distance of about 100 yards from the beach. The water at the hole was 17 feet deep at mean low water. The ice was level, and at the beginning of observations in February was  $4_6^{\circ}$  feet thick

and at the close of observations in June was 5 feet thick.

About one mile and a half from the beach and parallel with it is a bar having about 3 fathoms water upon it. On this bar the heavy pack-ice grounds and thus leaves the inshore ice comparatively andisturbed. During this entire series of observations the ice remained undisturbed except in elevation. The anchor remained unmoved and the line hung free in the middle of the hole. The accumulations of ice on the side of the hole were chopped away each day. That the ice, however, rose and fell was obvious, independent of the gauge readings, for along the "ice foot" at the beach the rise and fall was clearly seen, though there was never open water between the beach and the gauge, except for a few moments when the general level of ice would break off from the "ice feet" with falling or rising tide and make a narrow seam, which was soon after solidly frozen over.

In this location the gauge was practically free from local peculiarities and so disposed as to

give the fluctuations of level in the open ocean.

Fime.—The observations were made on local mean time. At intervals of one, two, or three weeks, as the weather permitted, time observations were made with transit or sextant, for the regulation of the standard chronometer upon which all other time-pieces depended.

Flood tides came from the southward and westward and there was a prevailing current setting to the northeast. The ebb current slackened but did not reverse this current.

The daily rise and fall of tide is quite small, being about 6 or 7 inches, but during the series of observations the level of the sea varied more than 3 feet.

he duplicate record has been placed in the hands of the superintendent of the Coast and Geodetic Survey for reduction, discussion, and publication. A preliminary discussion has been made, from which enough of the peculiarities of these Arctic tides have been brought out to show that a more complete analysis, study, and comparison with other Arctic tides is desirable. It has been deemed desirable to substitute here the original record of observations for this preliminary discussion and to give the full discussion hereafter. This discussion will be made and published by the Coast and Geodetic Survey.

Tidal observations at the United States International Polar Station, Uglaamie, Alasla, 1883.

## PART VIII.

MISCELLANEOUS OBSERVATIONS.

## MISCELLANEOUS OBSERVATIONS.

# I. A REPORT ON THE GROUND CURRENT OBSERVATIONS MADE AT UGLAAMIE, ALASKA.

By A. L. MCRAE, Private Signal Corps, U. S. Army.

The observations were commenced August 11, 1882, and were continued at hourly intervals until November 14, 1882.

The lines were insulated wires one thousand yards in length. One was in the magnetic meridian, and the other at right angles to it.

The terminals were copper plates 2 (1?) feet square. The N., S. and W. terminals were in water; the E. in land.

Compass galvanoscopes were used to measure the strength of the current.

As the observations possess especial interest because they were made in such a high latitude, several deflections of the galvanoscope have been reduced to something like absolute measure by comparison with a galvanometer in the laboratory.

Unfortunately the electromotive force due to the terminals and the resistance of the complete circuit were not determined, so that their effects cannot be accurately estimated.

But from an experiment with copper plates one square foot in area it was found that the electromotive force under the most favorable circumstances, when both plates were in sea is less than .05 volt, and when one plate was in sea and the other in land is less than .2 volt.

Mr. Wild has found that the electromotive force due to copper plates buried in the earth may reach .05 volt. We can therefore safely assume that the electromotive force between the plates used in the observations was not greater than .2 volts.

Mr. Wild has already found that the resistance of the ground between copper plates one square meter in area buried two meters below the surface and one kilometer apart was between thirty and sixty ohms. By comparison the resistance of the ground at Uglaamie would be between eighty and one hundred and sixty ohms. But since all the plates except one were in water it is probable the resistance was much less.

If we assume that the resistance of the line and the ground was so small compared to the resistance of the galvanoscope as to be inappreciable, we find that at times there was an electromotive force of .8 volt acting. Deducting the .2 due to the terminals we have .6 volt remaining, which must be due to a ground current.

The difficulties mentioned above of eliminating everything from the true ground current prevent a careful study of the observations; but by plotting the total current it appears that:

1. The current is generally steady in strength and direction for several days at a time. There are periods when there is no current. There are also rare moments when the intensity of the current changes rapidly. The direction of the current usually changes slowly.

2. The north and south component is the stronger.

3. The general direction of the current is from the first (NW.) to the third (SE.) quadrant, and not from the second (NE.) to the fourth (SW.) as in Europe.

The general direction varied from due west to a little east of north.

In connection with auroras it is noticed that:

On September 4 a weak variable current suddenly changed to a strong north by east current six or seven hours before an aurora was observed. This strong current continued for several days and auroras on the 6th, 12th, and 15th did not seem to affect its intensity or direction.

On September 25 there was quite a disturbance of the needle five hours in advance of the aurora. Just after the appearance of the aurora the current began to weaken and shifted from north to northwest.

On September 26 there was an increased current one hour in advance of the aurora.

On October 8 a westerly current changed to a little south of west one hour in advance of the aurora.

At other times auroras occurred when there was a strong or moderately strong current without apparently having the slightest effect.

#### NOTE ON AN IMPROVED METHOD FOR OBSERVING GROUND CURRENTS.

Heretofore the best method for observing ground currents has been that of two lines, one in the magnetic meridan and one at right angles to it. By this method the difference of potential between N, and S, and between E, and W, giving the components of the current in these two directions can be obtained. This, however, is not sufficient to enable us to determine the exact direction and strength of the current.

Now, if the difference of potential between N. and W. is taken at the same time as that of N. and S. and of E. and N., there will be all the necessary data to plat the equipotential surfaces, from which the direction of the current can be obtained.

Then, knowing distance between the equipotential surfaces, we can get the variation of the potential with respect to the distance and hence the strength of the current.

The lines need not be at right angles, nor is it necessary that one should be in the magnetic meridian.

#### II. THICKNESS OF THE ICE.

The thickness of the ice in the lagoon close to the station, and in the still water of the sea near shore, was measured at intervals of about a month during the winter.

The following table presents the results of these observations:

| LA  | GOON                       | ICE.               | A1                                   |
|---|----------------------------|--------------------|--------------------------------------|
